

STRONG PREFERENCES AFFECT THE ROBUSTNESS OF PREFERENCE MODELS AND VALUE ALIGNMENT

TL; DR

- We study the robustness of value alignment by analyzing the sensitivity of preference models, a core component of value alignment.
- We show that under the Plackett-Luce model, preference probabilities can change significantly due to small changes in the learned preference distribution.
- We characterize this sensitivity: it occurs with strong preferences with probabilities close to 0 and 1.

Introduction

We cannot Specify all the Preferences

Models could Learn Slightly Different Preferences

Question We Ask

How sensitive a preference probability is with respect to changes in other preference probabilities?

Assumptions for Pairwise Preference Models

- Asm 1:** Preference probabilities only depend on score differences $p_{ij} = p(y_i > y_j) = g(s_i - s_j), g \in \mathbb{R} \rightarrow (0,1)$
- Asm 2:** $g(x)$ is strictly increasing $\Leftrightarrow (s_i - s_j \uparrow \Leftrightarrow p_{ij} \uparrow)$
- Asm 3:** $\lim_{x \rightarrow -\infty} g(x) = 0, \lim_{x \rightarrow +\infty} g(x) = 1$
- Asm 4:** $\forall x \in \mathbb{R}, g(x) + g(-x) = 1 \Leftrightarrow p_{ij} + p_{ji} = 1$
- Asm 5:** $g(x)$ is continuously differentiable

Special case: Bradley-Terry model $g_{BT}(x) = \frac{1}{1+\exp(-x)}$

Measuring Sensitivity

Consider a multivariable function $h(\mathbf{x}) = h(x_1, x_2, \dots, x_L)$.

- **M-sensitivity:** $h(\mathbf{x})$ is M-sensitive to x_i at $\mathbf{x}'$ if $\left| \frac{\partial h}{\partial x_i} \Big|_{\mathbf{x}=\mathbf{x}'} \right| > M$.
- **M-sensitivity region of h :** $\Omega_M(h, x_i): \{\mathbf{x}' \in \text{Dom}(h): \left| \frac{\partial h}{\partial x_i} \Big|_{\mathbf{x}=\mathbf{x}'} \right| > M\}$.

Analysis for Pairwise Preference Models

Lemma 1 The unspecified p_{ij} is a function of p_{ik} and p_{kj} :

$$p_{ij} = g(s_i - s_j) = g(s_i - s_k + s_k - s_j) = g(g^{-1}(p_{ik}) + g^{-1}(p_{kj})) = p_{ij}(p_{ik}, p_{kj})$$

Theorem 1 For all $M > 0$, there exists $0 < p_0, p'_{kj} < 1$, such that $p_{ij}(p_{ik}, p'_{kj})$ is M-sensitive to p_{ik} for all $p_0 < p_{ik} < 1$. Similarly, there exists $0 < p_1, p''_{kj} < 1$, such that $p_{ij}(p_{ik}, p''_{kj})$ is M-sensitive to p_{ik} for all $0 < p_{ik} < p_1$.

- p_{ij} can be **arbitrarily sensitive** to p_{ik} when p_{ik} (and p_{kj}) are close to 0 or 1.

Characterizing Sensitivity for the Bradley-Terry (B-T) Model

- **When is B-T model sensitive?**

Back to the example:

$$(p_{ik}^A, p_{kj}^A) = (0.9999, 0.0200) \in \Omega_{48}(p_{ij}^{BT}, p_{ik}^{BT}) \quad (p_{ik}^B, p_{kj}^B) = (0.9801, 0.0200) \in \Omega_{12}(p_{ij}^{BT}, p_{ik}^{BT})$$

Extension to the Plackett-Luce Model

Let $\mathcal{O} = \{o_1, o_2, \dots, o_K\}$ be the set of all the options. Let $\omega = (o_{\omega_1}, o_{\omega_2}, \dots, o_{\omega_K}) \in \text{Perm}(\mathcal{O})$ be a preference over the options. Under the Plackett-Luce Model:

Lemma 5 Let ω be a K-tuple preference. Then $p_{\omega}^{(K)}$, under the Plackett-Luce Model, can be written as a function of $p_{\omega_{uv}}^{(K)}/p_{\omega_{vu}}^{(K)}$, where $1 \leq u, v \leq K$, $\omega_{uv} = (\omega'_{uv}; \omega_u, \omega_v)$ and $\omega_{vu} = (\omega'_{uv}; \omega_v, \omega_u)$, and ω'_{uv} is any $(K-2)$ -permutation of $\mathcal{O} \setminus \{\omega_u, \omega_v\}$:

$$p_{\omega}^{(K)} = \prod_{u=1}^{K-1} \frac{1}{1 + \sum_{v=u+1}^K p_{\omega_{uv}}^{(K)}/p_{\omega_{vu}}^{(K)}}$$

- **When is P-L model sensitive?**

$$0 < p_{\omega_{uv}}^{(K)} < \frac{\beta}{4\alpha M}, \gamma_1 - \gamma_2 < p_{\omega_{vu}}^{(K)} < \gamma_1 + \gamma_2$$

α, β are some constants γ_1, γ_2 are functions of $(M, p_{\omega_{uv}}^{(K)})$ (see Eqn. 11)

$$A(\Omega_M(p_{\omega}^{(K)}, p_{\omega_{uv}}^{BT})) = \frac{\beta^2}{6\alpha M^2}$$

Area of the region

Analysis

Comparing B-T and P-L Models

Theorem 2 For all $M > 1$ and $K > 2$:

$$A(\Omega_M(p_{ij}^{BT}, p_{ik}^{BT})) > A(\Omega_M(p_{\omega}^{(K)}, p_{\omega_{uv}}^{BT}))$$

Takeaways

- Preference models with similar behaviors on the training set may assign significantly different probabilities to unseen preferences.
- Minor changes in the data distributions within the training set may lead to significant changes in the learned preference models.
- P-L models (with $K > 2$) are more robust than B-T model.
- Not just for value alignment, but wherever PM is used (e.g., Chatbot Arena)

Experiments

Strong Preferences are not Uncommon

Frequencies of preference probabilities assigned by reward models on Anthropic/hh-rlhf

p_{ul}	Frequency of p_{ul}	
	Llama-3.1-Nemotron-70B-Reward-HF	reward-model-deberta-v3-large-v2
(0.00, 0.05)	1,184	22
(0.05, 0.10)	363	62
(0.10, 0.90)	3,636	7037
(0.90, 0.99)	1,574	1,264
(0.99, 1.00)	1,795	167
Total	8,552	

Sensitivities of Preference Models Manifest in Value Alignment

- Synthetic dataset: $\mathcal{O} = \{\text{dog, cat, bird}\}$ three preferences
- Set p_{12}^D to be 0.99 or 0.5 strong or moderate preferences
- Vary p_{23}^D from 0 to 1, resulting in changes in DPO-learned p_{13}^L
- Check the learned p_{13}^L , does it change proportionally to p_{23}^L ?
- Studied LLMs: Llama-3-8B-Instruct, zephyr-7b-alpha

$p_{12}^D = 0.99$: Despite small/no changes in p_{23}^L , a significant change in p_{13}^L occurs.

$p_{12}^D = 0.50$: p_{13}^L tends to change proportionally to p_{23}^L .
